# 1 Newton's Laws of Motion

## 1.2 Space and Time

- In cartesian coordinates the basis vectors don't depend on time so their derivatives are  $\mathbf{0}$ . This means that

$$\begin{aligned}\frac{d}{dt}(x\hat{\mathbf{x}} + y\hat{\mathbf{y}} + z\hat{\mathbf{z}}) &= \frac{dx}{dt}\hat{\mathbf{x}} + x\frac{d\hat{\mathbf{x}}}{dt} + \frac{dy}{dt}\hat{\mathbf{y}} + y\frac{d\hat{\mathbf{y}}}{dt} + \frac{dz}{dt}\hat{\mathbf{z}} + z\frac{d\hat{\mathbf{z}}}{dt} \\ &= \frac{dx}{dt}\hat{\mathbf{x}} + \frac{dy}{dt}\hat{\mathbf{y}} + \frac{dz}{dt}\hat{\mathbf{z}}\end{aligned}$$

as expected. However, in order coordinate systems (e.g. polar, spherical) the basis vectors may depend on time and their derivatives aren't  $\mathbf{0}$ .

## 1.4 Newton's First and Second Laws; Inertial Frames

- Newton's second law  $\mathbf{F} = m\mathbf{a}$  can be restated as  $\mathbf{F} = \dot{\mathbf{p}}$ .
- An inertial frame is one where Newton's first law holds. Typically this means the frame isn't accelerating or rotating.

## 1.5 The Third Law and Conservation of Momentum

- Forces that act along the line joining two objects are called **central forces**.
- The **principle of conservation of momentum** states that if the net external force  $\mathbf{F}_{\text{ext}}$  on an  $N$ -particle system is zero, the system's total momentum  $\mathbf{P}$  is constant.

## 1.7 Two-Dimensional Polar Coordinates

- In two-dimensional polar coordinates, the unit vectors  $\hat{\mathbf{r}}$  and  $\hat{\phi}$  depend on position and thus time. Their derivatives are

$$\begin{aligned}\frac{d\hat{\mathbf{r}}}{dt} &= \dot{\phi}\hat{\phi} \\ \frac{d\hat{\phi}}{dt} &= -\dot{\phi}\hat{\mathbf{r}}.\end{aligned}$$

Consequently, the derivatives of the position vector  $\mathbf{r} = r\hat{\mathbf{r}}$  are

$$\begin{aligned}\frac{d\mathbf{r}}{dt} &= \frac{d}{dt}(r\hat{\mathbf{r}}) \\ &= \dot{r}\hat{\mathbf{r}} + r\frac{d\hat{\mathbf{r}}}{dt} \\ &= \dot{r}\hat{\mathbf{r}} + r\dot{\phi}\hat{\boldsymbol{\phi}}\end{aligned}$$

and

$$\begin{aligned}\frac{d^2\mathbf{r}}{dt^2} &= \frac{d}{dt}(\dot{r}\hat{\mathbf{r}} + r\dot{\phi}\hat{\boldsymbol{\phi}}) \\ &= \ddot{r}\hat{\mathbf{r}} + \dot{r}\frac{d\hat{\mathbf{r}}}{dt} + \dot{r}\dot{\phi}\hat{\boldsymbol{\phi}} + r\ddot{\phi}\hat{\boldsymbol{\phi}} + r\dot{\phi}\frac{d\hat{\boldsymbol{\phi}}}{dt} \\ &= \ddot{r}\hat{\mathbf{r}} + \dot{r}\dot{\phi}\hat{\boldsymbol{\phi}} + \dot{r}\dot{\phi}\hat{\boldsymbol{\phi}} + r\ddot{\phi}\hat{\boldsymbol{\phi}} - r\dot{\phi}^2\hat{\mathbf{r}} \\ &= (\ddot{r} - r\dot{\phi}^2)\hat{\mathbf{r}} + (r\ddot{\phi} + 2\dot{r}\dot{\phi})\hat{\boldsymbol{\phi}}.\end{aligned}$$

- In light of the above, Newton's second law in polar coordinates can be written

$$\begin{aligned}F_r &= m(\ddot{r} - r\dot{\phi}^2) \\ F_\phi &= m(r\ddot{\phi} + 2\dot{r}\dot{\phi}).\end{aligned}$$

## 2 Projectiles and Charged Particles

### 2.1 Air Resistance

- Air resistance depends on the speed  $v$  of the moving object. For many objects the direction of the air resistance force  $\mathbf{f}$  is opposite to  $\mathbf{v}$ , but not always. For example, the air resistance force on an airplane causes lift.
- An air resistance force can be described by the equation

$$\mathbf{f} = -f(v)\hat{\mathbf{v}}$$

where  $\hat{\mathbf{v}} = \mathbf{v}/|\mathbf{v}|$  gives the direction and  $f(v)$  gives the magnitude.

- $f(v)$  can be approximated as

$$f(v) = f_{\text{lin}} + f_{\text{quad}} = bv + cv^2.$$

- The linear term  $f_{\text{lin}}$  arises from the viscous drag of the medium and is generally proportional to the projectile's linear size.
- The quadratic term  $f_{\text{quad}}$  arises from the fact that the projectile must accelerate the air with which it is continually colliding and it is proportional to the density of the medium and the cross-sectional area of the projectile.

- For a spherical projectile the coefficients  $b$  and  $c$  above have the form

$$b = \beta D \text{ and } c = \gamma D^2$$

where  $D$  is the diameter of the sphere and the coefficients  $\beta$  and  $\gamma$  depend on the nature of the medium. In air at STP they have approximate values

$$\beta = 1.6 \times 10^{-4} \text{ N s/m}^2$$

and

$$\gamma = 0.25 \text{ N s}^2/\text{m}^4.$$

- Depending on the natures of the medium and projectile it's often possible to neglect one of the terms in  $f(v)$ . To determine if this is the case we can calculate their ratio. For example, for a spherical projectile at STP

$$\frac{f_{\text{quad}}}{f_{\text{lin}}} = \frac{cv^2}{bv} = \frac{\gamma D}{\beta} v = (1.6 \times 10^3 \text{ s/m}^2) Dv.$$

If the ratio is large  $f_{\text{lin}}$  can be ignored. If it's small  $f_{\text{quad}}$  can be ignored.

- The **Reynolds number** can be used to characterise the behaviour of an object in a fluid

$$R = \frac{\rho}{\mu} Dv$$

where  $\rho$  is the medium's density,  $\mu$  is its viscosity,  $D$  is the linear dimension of the projectile (diameter for spherical projectiles), and  $v$  is the projectile's speed. The quadratic force  $f_{\text{quad}}$  is dominant when the Reynolds number  $R$  is large and the linear force  $f_{\text{linear}}$  is dominant when it is small.

## 2.2 Linear Air Resistance

- When the quadratic drag force is negligible the equation of motion becomes

$$\mathbf{F} = \mathbf{W} - \mathbf{f}$$

$$m\mathbf{a} = m\mathbf{g} - b\mathbf{v}$$

$$m\dot{\mathbf{v}} = m\mathbf{g} - b\mathbf{v}.$$

This is a first-order differential equation for  $\mathbf{v}$  where the horizontal and vertical components can be separated to

$$m\dot{v}_x = -bv_x$$

$$m\dot{v}_y = mg - bv_y,$$

each of which is easily solvable.

- The **terminal speed** of an object undergoing freefall and experiencing only linear drag is

$$v_{\text{ter}} = \frac{mg}{b}.$$

- The **characteristic time**

$$\tau = \frac{1}{k} = \frac{1}{b/m} = \frac{m}{b}$$

is a measure of the importance of air resistance.

- For horizontal motion with drag it's a measure of the time it takes for the projectile to reach  $1/e$  of its initial velocity.
- For freefall with drag it's a measure of the time it would take the projectile to reach its terminal velocity if it didn't experience drag

$$v_{\text{ter}} = g\tau.$$

- For freefall with drag it can also be used to gauge what percentage of its terminal velocity a projectile will reach after a certain time:

| Time $t$ | Percent of $v_{\text{ter}}$ |
|----------|-----------------------------|
| 0        | 0                           |
| $\tau$   | 63%                         |
| $2\tau$  | 86%                         |
| $3\tau$  | 95%                         |

From this it can be seen that after  $t = 3\tau$  the projectile has effectively reached its terminal velocity.

## 2.4 Quadratic Air Resistance

- Equations of motion for quadratic air resistance can be solved analytically when the projectile moves in one dimension, but can only be solved numerically when it moves in multiple dimensions.
- When a projectile moves in one dimension and only experiences the force of air resistance (i.e. there are no other forces), the equation of motion is

$$m\dot{v} = -cv^2.$$

Using separation of variables the solution can be found to be

$$v(t) = \frac{v_0}{1 + t/\tau}$$

where

$$\tau = \frac{m}{cv_0}.$$

- As in the linear case,  $\tau$  is a measure of how long it takes for air resistance to slow down the projectile ( $v = v_0/2$  at  $t = \tau$ ).
- Integrating the equation for  $v(t)$  gives

$$x(t) = v_0 \tau \ln \left( 1 + \frac{t}{\tau} \right).$$

- When a projectile moves in one dimension and experiences the forces of air resistance and weight, the equation of motion (with  $y$  down) is

$$m\dot{v} = mg - cv^2.$$

Using separation of variables the solution can be found to be

$$v(t) = v_{\text{ter}} \tanh \frac{gt}{v_{\text{ter}}}$$

where

$$v_{\text{ter}} = \sqrt{\frac{mg}{c}}.$$

- Integrating the equation for  $v(t)$  gives

$$y = \frac{v_{\text{ter}}^2}{g} \ln \left( \cosh \frac{gt}{v_{\text{ter}}} \right).$$

## 2.5 Motion of a Charge in a Uniform Magnetic Field

- When a particle of charge  $q$  moves in a magnetic field  $\mathbf{B} = (0, 0, B_z)$  with velocity  $\mathbf{v} = (v_x, v_y, v_z)$  it experiences a force

$$\mathbf{F} = q\mathbf{v} \times \mathbf{B} = q(v_y B, -v_x B, 0).$$

This gives the coupled equations of motion

$$\begin{aligned} m\dot{v}_x &= qBv_y \\ m\dot{v}_y &= -qBv_x \\ m\dot{v}_z &= 0 \end{aligned}$$

or

$$\begin{aligned} \dot{v}_x &= \omega v_y \\ \dot{v}_y &= -\omega v_x \\ \dot{v}_z &= 0 \end{aligned}$$

where  $\omega = qB/m$  is called the **cyclotron frequency**.

- If we define a complex value

$$\eta = v_x + iv_y,$$

its derivative is

$$\begin{aligned}\dot{\eta} &= \dot{v}_x + i\dot{v}_y \\ &= \omega v_y - i\omega v_x \\ &= -i\omega\eta\end{aligned}$$

which has the solution

$$\eta = Ae^{-i\omega t}.$$

### 3 Momentum and Angular Momentum

#### 3.1 Conservation of Momentum

- The **principle of conservation of momentum** states that if the net external force  $\mathbf{F}_{\text{ext}}$  on an  $N$ -particle system is zero, the system's total mechanical momentum  $\mathbf{P} = \sum m_\alpha \mathbf{v}_\alpha$  is constant.

#### 3.2 Rockets

- Newton's second law for a rocket is

$$m\dot{v} = -\dot{m}v_{\text{ex}}$$

where  $\dot{m}$  is the (negative) rate of change of the mass of the rocket and  $v_{\text{ex}}$  is the velocity of the exhaust. The quantity on the right hand side of the equation is called the **thrust**.

- The equation above can be solved by separation of variables giving

$$v - v_0 = v_{\text{ex}} \ln \frac{m_0}{m}$$

which is often called the **rocket equation**.

#### 3.3 The Center of Mass

- The **centre of mass** of a system is defined to be

$$\mathbf{R} = \frac{1}{M} \sum_{\alpha=1}^N m_\alpha \mathbf{r}_\alpha$$

where  $M$  is the total mass of all particles in the system,  $m_\alpha$  is the mass of particle  $\alpha$ , and  $\mathbf{r}_\alpha$  is the vector from the origin to particle  $\alpha$ .

- The total momentum of a system can be written in terms of its centre of mass

$$\mathbf{P} = \sum_{\alpha} \mathbf{p}_{\alpha} = \sum_{\alpha} m_{\alpha} \dot{\mathbf{r}}_{\alpha} = M \dot{\mathbf{R}}$$

i.e. the total momentum of  $N$  particles is equivalent to that of a single particle of mass  $M$  with velocity equal to that of the centre of mass.

- Differentiating the above we find

$$\begin{aligned} \frac{d}{dt} \mathbf{P} &= \frac{d}{dt} (M \dot{\mathbf{R}}) \\ \mathbf{F}_{\text{ext}} &= M \ddot{\mathbf{R}} \end{aligned}$$

i.e. the centre of mass moves as if it was a single particle of mass  $M$  subject to the net external force on the system.

- When a body is continuous the expression for its centre of mass becomes an integral

$$\mathbf{R} = \frac{1}{M} \int \mathbf{r} dm = \frac{1}{M} \int \rho \mathbf{r} dV.$$

### 3.4 Angular Momentum for a Single Particle

- The **angular momentum** of a particle relative to an origin  $O$  is

$$\mathbf{L} = \mathbf{r} \times \mathbf{p}$$

where  $\mathbf{r}$  is measured relative to  $O$ .

- Taking the derivative of angular momentum gives

$$\begin{aligned} \frac{d}{dt} \mathbf{L} &= \frac{d}{dt} (\mathbf{r} \times \mathbf{p}) \\ \dot{\mathbf{L}} &= \dot{\mathbf{r}} \times \mathbf{p} + \mathbf{r} \times \dot{\mathbf{p}} \\ &= \mathbf{r} \times \mathbf{F} \\ &= \boldsymbol{\tau}. \end{aligned}$$

In other words, the rate of change in angular momentum about an origin  $O$  is equal to the net torque about that origin.

- We can simplify some one-particle problems by choosing the origin such that the net torque is 0 and thus angular momentum is constant.

### 3.5 Angular Momentum for Several Particles

- The **total angular momentum** of a system is

$$\mathbf{L} = \sum_{\alpha=1}^N \mathbf{L}_{\alpha} = \sum_{\alpha=1}^N \mathbf{r}_{\alpha} \times \mathbf{p}_{\alpha}.$$

- Differentiating the above

$$\dot{\mathbf{L}} = \sum_{\alpha} \dot{\mathbf{L}}_{\alpha} = \sum_{\alpha} \mathbf{r}_{\alpha} \times \mathbf{F}_{\alpha} = \boldsymbol{\tau}_{\text{ext}}$$

we find that the rate of change of the total angular momentum of the system is equal to the net torque on the system.

- The **principle of conservation of angular momentum** states that if the net external torque on a system is 0, the system's total angular momentum is constant. This assumes that all internal forces are central and obey Newton's third law.
- The principle of conservation of momentum and the result  $\dot{\mathbf{L}} = \boldsymbol{\tau}_{\text{ext}}$  also hold if  $\mathbf{L}$  and  $\boldsymbol{\tau}_{\text{ext}}$  are measured about the centre of mass, even if the centre of mass is being accelerated and is thus not an inertial frame.

## 4 Energy

### 4.1 Kinetic Energy and Work

- The **work-kinetic-energy theorem** states that the change in a particle's kinetic energy between two points is equal to the work done by the net force on the particle between those two points

$$\Delta K = \int_1^2 \mathbf{F} \cdot d\mathbf{r}.$$

### 4.2 Potential Energy and Conservative Forces

- A force  $\mathbf{F}$  acting on a particle is considered **conservative** if:
  - $\mathbf{F}$  depends only on the particle's position  $\mathbf{r}$  (and not on its velocity  $\mathbf{v}$ , time  $t$ , or any other variable), and
  - for any two points 1 and 2, the work done by  $\mathbf{F}$  is the same for all paths between 1 and 2.
- Only conservative forces have associated **potential energy** functions.
- The potential energy function  $U(\mathbf{r})$  of a conservative force  $\mathbf{F}$  is defined as

$$U(\mathbf{r}) = - \int_{\mathbf{r}_0}^{\mathbf{r}} \mathbf{F}(\mathbf{r}') \cdot d\mathbf{r}'$$

where  $\mathbf{r}_0$  is an arbitrary point at which  $U(\mathbf{r}_0)$  is defined to be 0.

- The **principle of conservation of energy** states that if all the forces acting on a particle are conservative, each with its corresponding potential energy function  $U_i(\mathbf{r})$ , the **total mechanical energy**

$$E = K + U = K + U_1(\mathbf{r}) + \cdots + U_n(\mathbf{r}),$$

is constant in time.

- If nonconservative forces do work then the total energy of the system changes by that amount

$$\Delta E = W_{\text{nc}}.$$

### 4.3 Force as the Gradient of Potential Energy

- A conservative force  $\mathbf{F}$  can be expressed as the negative gradient of its potential energy function  $U$

$$\mathbf{F} = -\nabla U.$$

### 4.4 The Second Condition that $\mathbf{F}$ be Conservative

- A force  $\mathbf{F}$  is conservative if  $\nabla \times \mathbf{F} = \mathbf{0}$ .

### 4.5 Time-Dependent Potential Energy

- If a time-dependent force  $\mathbf{F}(t)$  has the property  $\nabla \times \mathbf{F}(t) = \mathbf{0}$  it's still possible to define an associated potential energy function  $U(\mathbf{r}, t)$  where  $\mathbf{F}(t) = -\nabla U(t)$  but it's no longer guaranteed that total mechanical energy is conserved over time.

### 4.8 Central Forces

- A central force is conservative if and only if it's spherically symmetric.

## 5 Oscillations

### 5.2 Simple Harmonic Motion

- The equation of motion for a harmonic oscillator

$$\ddot{x} = -\frac{k}{m}x = -\omega^2 x$$

can be solved in multiple ways:

– the exponential solution

$$x = c_1 e^{i\omega t} + c_2 e^{-i\omega t},$$

- the sine and cosine solutions

$$x = c_1 \cos \omega t + c_2 \sin \omega t,$$

and

- the phase shifted cosine solution

$$x = A \cos(\omega t - \delta)$$

where

$$A = \sqrt{c_1^2 + c_2^2}$$

with  $c_1$  and  $c_2$  coming from the sine and cosine solutions above and

$$\delta = \arctan -\frac{c_1}{c_2}.$$

### 5.3 Two-Dimensional Oscillators

- An **isotropic harmonic oscillator** in  $n > 1$  dimensional space experiences a restoring force directed towards the equilibrium position and with magnitude  $kr$  where  $r$  is the object's distance from equilibrium.
- In two dimensions an isotropic harmonic oscillator has general solutions

$$\begin{aligned} x(t) &= A_x \cos \omega t \\ y(t) &= A_y \cos(\omega t - \delta). \end{aligned}$$

It was possible to eliminate the phase from  $x(t)$  by redefining the origin of time but in general it isn't possible to also eliminate the phase from  $y(t)$ .

- An **anisotropic harmonic oscillator** is similar to an isotropic harmonic oscillator but the spring constants are different in different directions.

### 5.7 Fourier Series

- Any periodic function with period  $T$  can be represented as a Fourier series

$$f(t) = \sum_{n=0}^{\infty} [a_n \cos(n\omega t) + b_n \sin(n\omega t)]$$

where

$$\begin{aligned}a_0 &= \frac{1}{T} \int_{-T/2}^{T/2} f(t) dt \\a_n &= \frac{2}{T} \int_{-T/2}^{T/2} f(t) \cos(n\omega t) dt \\b_0 &= 0 \\b_n &= \frac{2}{T} \int_{-T/2}^{T/2} f(t) \sin(n\omega t) dt \\\omega &= \frac{2\pi}{T}.\end{aligned}$$

## 6 Calculus of Variations

- A **functional** is a mapping from a space  $X$  to the real or complex numbers. When  $X$  is the space of functions a functional is a “function of a function”, i.e. it takes a function as an argument.
- The goal of the **calculus of variations** is to find maxima and minima of functionals, i.e. functions that maximise or minimise the value of the functional. This is analogous to finding real numbers that maximise or minimise a function in single-variable calculus.
- A functional of the form

$$S = \int_{x_1}^{x_2} f[x, y(x), y'(x)] dx$$

can be solved using the **Euler-Lagrange equation**

$$\frac{\partial f}{\partial y} - \frac{d}{dx} \frac{\partial f}{\partial y'} = 0.$$

- A solution to the Euler-Lagrange equation isn't guaranteed to be a minimum — it could be a maximum or an inflection point, as in single-variable calculus. In general it's difficult to determine the nature of a given solution so other methods (e.g. inspection) must be used.
- A functional with multiple functions as arguments, e.g.

$$S = \int_{t_1}^{t_2} f[t, x(t), x'(t), y(t), y'(t)] dt,$$

results in a Euler-Lagrange equation for each function, e.g.

$$\begin{aligned}\frac{\partial f}{\partial x} - \frac{d}{dt} \frac{\partial f}{\partial x'} &= 0 \\\frac{\partial f}{\partial y} - \frac{d}{dt} \frac{\partial f}{\partial y'} &= 0.\end{aligned}$$

These can then be solved as above.

- Under Lagrangian mechanics, the independent variable is time  $t$  and the dependent variable(s) depend on the system under consideration. In general they're denoted  $q_1, q_2, \dots, q_n$  and are called **generalized coordinates**.

## 7 Lagrange's Equations

- Lagrangian mechanics has two advantages over Newtonian mechanics:
  - Lagrange's equations have the same form in all coordinate systems, and
  - Lagrange's equations omit the forces of constraint (e.g. the normal force that keeps a bead on a wire), simplifying calculations.

### 7.1 Lagrange's Equations for Unconstrained Motion

- The **Lagrangian function** or **Lagrangian** is defined as

$$\mathcal{L} = K - U,$$

i.e. the kinetic energy minus the potential energy.

- **Hamilton's principle** states that the actual path taken by a particle between points 1 and 2 in a given time interval  $t_1$  to  $t_2$  is such that the action integral

$$S = \int_{t_1}^{t_2} \mathcal{L} dt$$

is stationary when taken along the actual path, i.e. the actual path is the solution of the Euler-Lagrange equation when applied to the Lagrangian.

- A Lagrangian can be written in terms of any **generalized coordinates**  $q_1, q_2, q_3$  providing each position  $\mathbf{r}$  corresponds to a unique value  $(q_1, q_2, q_3)$  and vice versa.
- The derivative of the Lagrangian with respect to  $x$

$$\frac{\partial \mathcal{L}}{\partial x} = \frac{\partial}{\partial x}(K - U) = \frac{\partial}{\partial x} \left( \frac{1}{2}m(\dot{x}^2 + \dot{y}^2) - U(x, y) \right) = -\frac{\partial U(x, y)}{\partial x} = F_x$$

is the  $x$  component of the force while the derivative with respect to  $\dot{x}$

$$\frac{\partial \mathcal{L}}{\partial \dot{x}} = \frac{\partial}{\partial \dot{x}}(K - U) = \frac{\partial}{\partial \dot{x}} \left( \frac{1}{2}m(\dot{x}^2 + \dot{y}^2) - U(x, y) \right) = m\dot{x} = p_x$$

is the  $x$  component of the momentum. The same applies to the  $y$  and  $z$  dimensions. When generalized coordinates  $q_1, q_2, q_3$  are used the corresponding values behave like forces and momenta and are called **generalized forces** and **generalized momenta**, respectively.

- Another way of stating the above is

$$\frac{\partial \mathcal{L}}{\partial q_i} = (\textit{ith component of generalized force})$$

and

$$\frac{\partial \mathcal{L}}{\partial \dot{q}_i} = (\textit{ith component of generalized momentum}).$$

Using this terminology, the Euler-Lagrange equation

$$\frac{\partial \mathcal{L}}{\partial q_i} = \frac{d}{dt} \frac{\partial \mathcal{L}}{\partial \dot{q}_i}$$

takes the form

$$(\textit{generalized force}) = (\textit{rate of change of generalized momentum}).$$

- For example, in 2D polar coordinates  $(r, \phi)$  the generalized force for the  $\phi$  coordinate is the torque on the particle and the generalized momentum is the angular momentum.
- Conservation laws can be derived from the Euler-Lagrange equations in generalized coordinates. For example, if the  $i$ th component of the generalized force is zero

$$\frac{\partial \mathcal{L}}{\partial q_i} = 0$$

then the rate of change of the  $i$ th component of the generalized momentum is also zero and thus it doesn't change.

- If the relationship between  $\mathbf{r}$  and the generalized coordinates  $q_1, q_2, \dots, q_n$  doesn't involve  $t$  the generalized coordinates are called **natural** and have some additional properties.
- The number of **degrees of freedom** of a system is the number of coordinates that can be independently varied in a small displacement, i.e. the number of independent "directions" in which the system can move from any given initial configuration.
- When the number of degrees of freedom of an  $N$  particle system is less than  $3N$  (or  $2N$  in two dimensions), the system is said to be **constrained**.
- When the number of degrees of freedom of a system matches the number of generalized coordinates required to model the system, it is said to be **holonomic**.
- In order to apply Lagrange's equations to a system its constraints must be holonomic, i.e. they must be expressible in the form

$$f(q_1, q_2, \dots, q_n, t) = 0.$$

- The generalized coordinates can be measured relative to a non-inertial reference frame providing the Lagrangian  $\mathcal{L} = K - U$  is originally written as inertial.

## 7.6 Generalized Momenta and Ignorable Coordinates

- When the Lagrangian is independent of a coordinate  $q_i$ , that coordinate is said to be **ignorable** or **cyclic**. When choosing coordinates, it is desirable to make as many ignorable as possible.

## 7.8 More about Conservation Laws

- If the Lagrangian is unchanged by spacial translation, the total momentum of the system is conserved.
- If the Lagrangian is unchanged by time translation, the total energy of the system is conserved.

## 7.9 Lagrange's Equations for Magnetic Forces

- For a given mechanical system with generalized coordinates  $q = (q_1, \dots, q_n)$ , a **Lagrangian**  $\mathcal{L}$  is a function  $\mathcal{L}(q_1, \dots, q_n, \dot{q}_1, \dots, \dot{q}_n, t)$  of the coordinates and velocities, such that the correct equations of motion for the system are the Lagrange equations

$$\frac{\partial \mathcal{L}}{\partial q_i} = \frac{d}{dt} \frac{\partial \mathcal{L}}{\partial \dot{q}_i} \text{ for } i = 1, \dots, n.$$

- It's important to note that the above does not define a unique Lagrangian function — any function  $\mathcal{L}$  that gives the correct equations of motion is valid and has all the correct properties.
- The Lagrangian for a particle of charge  $q$  and mass  $m$  moving in electric and magnetic fields  $\mathbf{E}$  and  $\mathbf{B}$  is

$$\mathcal{L} = \frac{1}{2} m \dot{\mathbf{r}}^2 - q(V - \dot{\mathbf{r}} \cdot \mathbf{A}).$$

# 8 Two-Body Central Force Problems

## 8.1 The Problem

- If two objects that experience a conservative central force, their potential energy depends only on the distance between them

$$U(\mathbf{r}_1, \mathbf{r}_2) = U(|\mathbf{r}_1 - \mathbf{r}_2|) = U(r)$$

and thus the Lagrangian is

$$\mathcal{L} = \frac{1}{2} m_1 \dot{r}_1^2 + \frac{1}{2} m_2 \dot{r}_2^2 - U(r).$$
