- (a) **0**
- (b) The same as if only the opposite charge were present all others are cancelled out.

$$\mathbf{E} = \frac{1}{4\pi\epsilon_0} 2 \frac{q}{2^2} \cos \theta \hat{\mathbf{x}}$$
$$= \frac{1}{4\pi\epsilon_0} \frac{dq}{[(d/2)^2 + z^2]^{3/2}} \hat{\mathbf{x}}$$

#### 2.4

The electric field a distance z above the midpoint of a line segment of length 2L and uniform line charge  $\lambda$  is

$$\mathbf{E} = \frac{1}{4\pi\epsilon_0} \frac{2\lambda L}{z\sqrt{z^2 + L^2}} \hat{\mathbf{z}}.$$

Applying this to the four sides of the square, the horizontal components of opposite sides cancel leaving only the vertical component.

$$\cos \theta = \frac{z}{z}$$

$$= \frac{z}{\sqrt{(a/2)^2 + z^2}}$$

$$\mathbf{E} = 4 \left( \frac{1}{4\pi\epsilon_0} \frac{\lambda a}{\sqrt{(a/2)^2 + z^2} \sqrt{(a/2)^2 + (a/2)^2 + z^2}} \hat{\mathbf{z}} \right) \cos \theta$$

$$= \frac{1}{4\pi\epsilon_0} \frac{4a\lambda z}{[(a/2)^2 + z^2] \sqrt{(a^2/2) + z^2}} \hat{\mathbf{z}}$$

$$\mathbf{E} = \frac{1}{4\pi\epsilon_0} \int_0^{2\pi} \frac{\lambda r}{r^2 + z^2} \cos\alpha \, d\theta \, \hat{\mathbf{z}}$$
$$= \frac{1}{4\pi\epsilon_0} \frac{2\pi\lambda rz}{(r^2 + z^2)^{3/2}} \hat{\mathbf{z}}$$

2.6

$$\begin{split} \mathbf{E} &= \frac{1}{4\pi\epsilon_0} \int \frac{dq}{\mathbf{r}^2} \cos\theta \hat{\mathbf{z}} \\ &= \frac{1}{4\pi\epsilon_0} \int_0^{2\pi} \int_0^R \frac{\sigma}{r^2 + z^2} \frac{z}{\sqrt{r^2 + z^2}} r \, dr \, d\theta \hat{\mathbf{z}} \\ &= \frac{1}{4\pi\epsilon_0} 2\pi\sigma z \int_0^R \frac{r}{(r^2 + z^2)^{3/2}} \, dr \, \hat{\mathbf{z}} \\ &= \frac{1}{4\pi\epsilon_0} 2\pi\sigma z \left(\frac{1}{z} - \frac{1}{\sqrt{R^2 + z^2}}\right) \hat{\mathbf{z}} \end{split}$$

When  $R \to \infty$ 

$$\mathbf{E} = \frac{\sigma}{2\epsilon_0} \hat{\mathbf{z}}.$$

2.7

$$\mathbf{E} = \begin{cases} \frac{1}{4\pi\epsilon_0} \frac{q}{z^2} \hat{\mathbf{z}} & z > R \\ \mathbf{0} & z < R \end{cases}$$

2.8

$$\mathbf{E} = \begin{cases} \frac{1}{4\pi\epsilon_0} \frac{q}{z^2} \hat{\mathbf{z}} & z > R \\ \frac{1}{4\pi\epsilon_0} \frac{qz}{R^3} \hat{\mathbf{z}} & z < R \end{cases}$$

2.9

$$\rho = \epsilon_0 \nabla \cdot \mathbf{E}$$

$$= \epsilon_0 \frac{1}{r^2} \frac{\partial}{\partial r} (kr^5)$$

$$= 5\epsilon_0 kr^2$$

$$Q_{\text{enc}} = \epsilon_0 \oint \mathbf{E} \cdot d\mathbf{a}$$

$$= \epsilon_0 \int_0^{2\pi} \int_0^{\pi} kR^3 R \, d\theta R \sin \theta \, d\phi$$

$$= 2\pi \epsilon_0 kR^5 [-\cos \theta]_0^{\pi}$$

$$= 4\pi \epsilon_0 kR^5$$

$$Q_{\text{enc}} = \int_V \rho \, d\tau$$

$$= \int_0^{2\pi} \int_0^{\pi} \int_0^R 5\epsilon_0 kr^2 \, drr \, d\theta r \sin \theta \, d\phi$$

$$= 10\pi \epsilon_0 k \int_0^{\pi} \int_0^R r^4 \sin \theta \, dr \, d\theta$$

$$= 2\pi \epsilon_0 kR^5 [-\cos \theta]_0^{\pi}$$

$$= 4\pi \epsilon_0 kR^5$$

If the charge was surrounded by 8 such cubes the total flux through all the cubes would be  $q/\epsilon_0$ . There are 24 outside faces to the larger cube, so the total flux through the shaded face is  $q/(24\epsilon_0)$ .

$$\int \mathbf{E}_{\text{inside}} \cdot d\mathbf{a} = \frac{Q_{\text{enc}}}{\epsilon_0}$$

$$= 0$$

$$\mathbf{E}_{\text{inside}} = \mathbf{0}$$

$$\int \mathbf{E}_{\text{outside}} \cdot d\mathbf{a} = \frac{Q_{\text{enc}}}{\epsilon_0}$$

$$4\pi r^2 E_{\text{outside}} = \frac{4\pi R^2 \sigma}{\epsilon_0}$$

$$\mathbf{E}_{\text{outside}} = \frac{1}{4\pi \epsilon_0} \frac{q}{r^2} \hat{\mathbf{r}}$$

$$\int \mathbf{E} \cdot d\mathbf{a} = \frac{Q_{\text{enc}}}{\epsilon_0}$$
$$4\pi r^2 E = \frac{\frac{4}{3}\pi r^3 \rho}{\epsilon_0}$$
$$\mathbf{E} = \frac{r\rho}{3\epsilon_0} \hat{\mathbf{r}}$$

By Gauss's law, the electric field of each plate is

$$\oint \mathbf{E} \cdot d\mathbf{a} = \frac{Q_{\text{enc}}}{\epsilon_0}$$
$$2A'E = \frac{A'\frac{Q}{A}}{\epsilon_0}$$
$$\mathbf{E} = \frac{Q}{2A\epsilon_0}\hat{\mathbf{n}}$$

so the field between the plates is zero and the field outside is  $Q/A\epsilon_0\hat{\mathbf{n}}$ , resulting in a pressure of

$$\begin{split} P &= \frac{\epsilon_0}{2} E^2 \\ &= \frac{\epsilon_0}{2} \frac{Q^2}{A^2 \epsilon_0^2} \\ &= \frac{Q^2}{2A^2 \epsilon_0} \end{split}$$

$$\begin{split} \mathbf{E}_{\mathrm{above}} &= \frac{1}{4\pi\epsilon_0} \frac{Q}{r^2} \hat{\mathbf{r}} \\ \mathbf{f} &= \frac{1}{2} \sigma \mathbf{E}_{\mathrm{above}} \\ &= \frac{1}{2} \frac{Q}{4\pi R^2} \frac{1}{4\pi\epsilon_0} \frac{Q}{R^2} \hat{\mathbf{r}} \\ &= \frac{Q^2}{32\pi^2 \epsilon_0 R^4} \hat{\mathbf{r}} \\ \mathbf{F} &= \int_0^{2\pi} \int_0^{\pi/2} \frac{Q^2}{32\pi^2 \epsilon_0 R^4} \cos \theta R^2 \sin \theta \, d\theta \, d\phi \hat{\mathbf{z}} \\ &= \frac{Q^2}{16\pi\epsilon_0 R^2} \int_0^{\pi/2} \cos \theta \sin \theta \, d\theta \hat{\mathbf{z}} \\ &= \frac{Q^2}{32\pi\epsilon_0 R^2} \hat{\mathbf{z}} \end{split}$$

$$\begin{split} \oint \mathbf{E} \cdot d\mathbf{a} &= \frac{Q}{\epsilon_0} \\ 2\pi s L E &= \frac{Q}{\epsilon_0} \\ \mathbf{E} &= \frac{Q}{2\pi L \epsilon_0} \frac{1}{s} \hat{\mathbf{s}} \\ V &= -\int_b^a \frac{Q}{2\pi \epsilon_0 L} \frac{1}{s} \, dr \\ &= \frac{Q}{2\pi \epsilon_0 L} \ln \frac{b}{a} \\ C &= \frac{Q}{V} \\ &= \frac{2\pi \epsilon_0 L}{\ln b/a} \end{split}$$

So the capacitance per unit length is

## 3 Potentials

#### 3.1

$$\begin{split} V_{\text{ave}} &= \frac{q}{4\pi\epsilon_0} \frac{1}{2zR} \sqrt{z^2 + R^2 - 2zR\cos\theta} \Big|_0^{\pi} \\ &= \frac{q}{4\pi\epsilon_0} \frac{1}{2zR} \left( \sqrt{z^2 + R^2 + 2zR} - \sqrt{z^2 + R^2 - 2zR} \right) \\ &= \frac{q}{4\pi\epsilon_0} \frac{1}{2zR} \left( \sqrt{(z+R)^2} - \sqrt{(R-z)^2} \right) \\ &= \frac{q}{4\pi\epsilon_0} \frac{1}{2zR} (z+R-R+z) \\ &= \frac{1}{4\pi\epsilon_0} \frac{q}{R} \end{split}$$

The average potential due to external charges is  $V_{\rm center}$  and the average potential due to internal charges is

$$\frac{1}{4\pi\epsilon_0} \frac{Q_{\rm enc}}{R}$$

SO

$$V_{\rm ave} = V_{\rm center} + \frac{1}{4\pi\epsilon_0} \frac{Q_{\rm enc}}{R}$$

A stable equilibrium is a minimum of potential energy. Laplace's equation doesn't allow for minimums, so they must be saddle points and the charge can escape.

$$0 = \nabla^{2}V$$

$$= \frac{1}{r^{2}} \frac{\partial}{\partial r} \left( r^{2} \frac{\partial V}{\partial r} \right)$$

#### 3.11

You need three charges: -q at (-a,b), -q at (a,-b), and q at (-b,-a). The potential is

$$V = \frac{1}{4\pi\epsilon_0} q \left( \frac{1}{\sqrt{(x-a)^2 + (y-b)^2}} - \frac{1}{\sqrt{(x+a)^2 + (y-b)^2}} - \frac{1}{\sqrt{(x-a)^2 + (y+b)^2}} + \frac{1}{\sqrt{(x+a)^2 + (y+b)^2}} \right).$$

The force on q is

$$\mathbf{F} = \frac{q^2}{16\pi\epsilon_0} \left[ \left( \frac{a}{(a^2 + b^2)^{3/2}} - \frac{1}{a^2} \right) \,\hat{\mathbf{x}} + \left( \frac{b}{(a^2 + b^2)^{3/2}} - \frac{1}{b^2} \right) \,\hat{\mathbf{y}} \right].$$

The work to bring q in from infinity is

$$W = \frac{q^2}{16\pi\epsilon_0} \left( \frac{1}{\sqrt{a^2 + b^2}} - \frac{1}{a} - \frac{1}{b} \right).$$

#### 3.12

Two infinitely long wires running parallel to the x-axis a distance 2a apart with charge densities  $\lambda$  and  $-\lambda$  have cylindrical equipotential surfaces with centres at

$$y_0 = \pm a \coth \frac{2\pi\epsilon_0 V_0}{\lambda}$$

radii

$$R = a \operatorname{csch} \frac{2\pi\epsilon_0 V_0}{\lambda}.$$

We know the equipotential surfaces (the pipes) and want to find the wires so we can find the potential, so

$$d = a \coth \frac{2\pi\epsilon_0 V_0}{\lambda}$$

$$R = a \operatorname{csch} \frac{2\pi\epsilon_0 V_0}{\lambda}$$

$$\frac{d}{R} = \cosh \frac{2\pi\epsilon_0 V_0}{\lambda}$$

$$\operatorname{arcosh} \frac{d}{R} = \frac{2\pi\epsilon_0 V_0}{\lambda}$$

$$\lambda = \frac{2\pi\epsilon_0 V_0}{\operatorname{arcosh} d/R}$$

$$R = a \operatorname{csch} \operatorname{arcosh} \frac{d}{R}$$

$$a = \frac{R}{\operatorname{csch} \operatorname{arcosh} d/R}$$

$$= (d+R)\sqrt{\frac{2d}{d+R} - 1}$$

$$= \sqrt{d^2 - R^2}$$

thus the potential is

$$V = \frac{V_0}{2\operatorname{arcosh} d/R} \ln \frac{(y+d^2-R^2)^2 + z^2}{(y-d^2+R^2)^2 + z^2}.$$

#### 4.30

The electric field is perpendicular to each plate and "curves" towards the other. At y=0 the electric field is purely vertical.  $\mathbf{p}$  only has a y component so  $(\mathbf{p} \cdot \nabla)\mathbf{E} = p_y \nabla E_y$ . The potential difference between the two plates is constant and as x increases the distance between them also increases, meaning the magnitude of the electric field decreases.  $E_y$  is negative at y=0 so this means it increases with increasing x and thus that the x component of  $\nabla E_y$  is positive.  $E_y$  is constant for small changes in y around y=0 so the y component of  $\nabla E_y$  is 0. We assume the plates are very long in the z direction so the z component of  $\nabla E_y$  is also 0. This means the dipole experiences a force in the x direction.

It's tricky to calculate the flux of the small loop's magnetic field through the big loop, so let's calculate the other way around.

$$\begin{split} B &= \frac{\mu_0 I}{2\pi s} \\ B_{\text{total}} &= \frac{\mu_0 I}{2\pi} \left( \frac{1}{s} + \frac{1}{3a - s} \right) \\ \Phi &= \frac{\mu_0 a I}{2\pi} \int_a^{2a} \left( \frac{1}{s} + \frac{1}{3a - s} \right) \, ds \\ &= \frac{\mu_0 a I}{2\pi} [\ln s - \ln(3a - s)]_a^{2a} \\ &= \frac{\mu_0 a I}{2\pi} [\ln 2a - \ln a - \ln a + \ln 2a] \\ &= \frac{\mu_0 a I}{\pi} \ln 2 \\ M &= \frac{\mu_0 a \ln 2}{\pi} \\ \mathcal{E} &= -M \frac{dI}{dt} \\ &= -\frac{\mu_0 a k \ln 2}{\pi} \end{split}$$

If the current in the larger loop flows counterclockwise the current in the smaller loop flows clockwise, so the answer is counterclockwise.

(a)

$$\begin{aligned} -\frac{\partial \mathbf{B}}{\partial t} &= \nabla \times \mathbf{E} \\ &= \nabla \times \mathbf{0} \\ &= \mathbf{0} \end{aligned}$$

Therefore **B** is independent of t.

$$-\frac{\partial}{\partial t} \int \mathbf{B} \cdot d\mathbf{a} = \oint \mathbf{E} \cdot d\mathbf{l}$$
$$-\frac{d\Phi_b}{dt} = 0$$

(c) Ampère's law with Maxwell's correction is

$$\nabla \times \mathbf{B} = \mu_0 \mathbf{J} + \mu_0 \epsilon_0 \frac{\partial \mathbf{E}}{\partial t}$$

but  ${\bf B}$  and  ${\bf E}$  are both 0 so

$$J = 0$$
.

(d) The magnetic field inside a sphere of radius R and surface charge density  $\sigma$  rotating at angular velocity  $\omega$  is

$$\mathbf{B} = \frac{2}{3}\mu_0 \sigma R\omega \,\hat{\mathbf{z}}.$$

In order to cancel the external magnetic field it must be the case that

$$B_0 + \frac{2}{3}\mu_0 \sigma R\omega = 0.$$

The surface charge density of the rotating sphere is

$$\mathbf{K} = \sigma \mathbf{v}$$
$$= \sigma \omega R \sin \theta \,\hat{\boldsymbol{\phi}}$$

but

$$\sigma\omega R\sin\theta = -\frac{3B_0\sin\theta}{2\mu_0}$$

(b) If a circular loop of radius R is in a uniform magnetic field in the z direction and that magnetic field changes, the induced electric field is

$$\mathbf{E} = -\frac{1}{2}R\frac{dB}{dt}\,\hat{\boldsymbol{\phi}}.$$

A sphere can be considered a stack of circular loops, so the torque on the sphere as the magnetic field changes is

$$\begin{split} \boldsymbol{\tau} &= \int_0^\pi 2\pi s (\mathbf{s} \times \mathbf{F}) R \, d\theta \\ &= \int_0^\pi 2\pi s^2 \sigma \left( -\frac{1}{2} s \frac{dB}{dt} \right) R \, d\theta \, \hat{\mathbf{z}} \\ &= -\pi \sigma R \frac{dB}{dt} \int_0^\pi (R \sin \theta)^3 \, d\theta \, \hat{\mathbf{z}} \\ &= -\frac{4}{3} \pi \sigma R^4 \frac{dB}{dt} \, \hat{\mathbf{z}}. \end{split}$$

The surface charge density and torque of sphere a is

$$\sigma_a = \frac{Q}{4\pi a^2}$$

$$\boldsymbol{\tau}_a = -\frac{1}{3}Qa^2\frac{dB}{dt}\,\hat{\mathbf{z}}$$

and the same for sphere b is

$$\sigma_b = -rac{Q}{4\pi b^2} \ oldsymbol{ au}_b = rac{1}{3}Qb^2rac{dB}{dt}\,\hat{f z}$$

so the total torque is

$$\boldsymbol{\tau} = \frac{1}{3} Q \frac{dB}{dt} (b^2 - a^2) \,\hat{\mathbf{z}}.$$

Integrating this over all time to find the change in angular momentum gives

$$\mathbf{L} = \int_0^\infty \boldsymbol{\tau} \, dt$$
$$= \frac{1}{3} Q(b^2 - a^2) \int_0^\infty \frac{dB}{dt} \, dt \, \hat{\mathbf{z}}$$
